

Balanced Binary Search Trees and `std::Set`

DAVID HAN DLHAN2@ILLINOIS.EDU

What is a set?

- ▶ Set (math) - **unordered** collection of **unique** objects
- ▶ `std::set` (C++) - **ordered** collection of **unique** objects

	Ordered	Unordered
No Duplicates	<code>std::set</code>	<code>std::unordered_set</code>
Duplicates	<code>std::multiset</code>	<code>std::unordered_multiset</code>

- ▶ Under the hood – `std::set` is implemented as a balanced binary search tree (BST)

Binary Search Tree

- ▶ A rooted tree where each node has ≤ 2 children
- ▶ Each node maintains a value and pointers to left and right child
- ▶ For any node x :
 - ▶ Value of left child $<$ value of x
 - ▶ Value of right child $>$ value of x

Operations Supported

- ▶ Insert
- ▶ Erase
- ▶ Find
- ▶ Begin
- ▶ Lower bound
- ▶ Size

Set::find(T x)

- ▶ Start from the root
- ▶ Repeatedly traverse down the tree
 - ▶ If $x ==$ current node value, found!
 - ▶ If $x <$ current node value, go to left child
 - ▶ If $x >$ current node value, go to right child
- ▶ If at any point we cannot go further but haven't found x , x doesn't exist in our BST. (`std::set::find` returns `set::end()` iterator)
- ▶ Otherwise, we return iterator to the node found

Find 7

► Source: Wikipedia

Set::insert(T x)

- ▶ Start from the root
- ▶ Repeatedly traverse down the tree
 - ▶ If $x ==$ current node value, we are done (no inserts)!
 - ▶ If $x <$ current node value, go to left child
 - ▶ If $x >$ current node value, go to right child

Insert 2

► Source: Wikipedia

Set::erase(T x)

- ▶ Find the node
 - ▶ If node is a leaf, just erase it
 - ▶ If it has one child, parent node now points to its child and we delete the node itself
 - ▶ If it has two children, swap it with the smallest element in the right subtree (go right, then repeatedly go left)

Erase 1

► Source: Wikipedia

Erase 10

► Source: Wikipedia

Erase 3

► Source: Wikipedia

Set::lower_bound(T x)

- ▶ Find smallest node $\geq x$.
- ▶ Start from the root
- ▶ Repeatedly traverse down the tree
 - ▶ If $x \leq$ current node value, set current node as the smallest node so far and go to left child
 - ▶ Else, go to right child
- ▶ Return smallest node

Lower bound 5

► Source: Wikipedia

BST worst case

- ▶ Suppose we inserted numbers 1, 2, 3, ..., n in that order.
 - ▶ What does our BST look like?
 - ▶ What is the runtime for find/insert/delete?
- ▶ Our BST becomes a linked list :(

Solution to BST worst case - Balanced BST

- ▶ Idea (balancing): try to keep each layer of the tree quite “full” and minimize tree height
 - ▶ It turns out we can maintain $O(\log n)$ tree height
- ▶ Many types of balanced BST, such as:
 - ▶ Red-black tree (STL implementation)
 - ▶ AVL tree (Relatively easy to implement)
 - ▶ Splay tree
 - ▶ Treap
 - ▶ Scapegoat tree
- ▶ We will talk about AVL trees

AVL tree

- ▶ Invariant: for any node, $|\text{right subtree height} - \text{left subtree height}| < 2$
- ▶ When is the invariant rule broken?
 - ▶ Insertions
 - ▶ Deletions
- ▶ If the invariant rule is broken, what is the height difference?
 - ▶ Always 2
- ▶ How to rebalance height difference 2?
 - ▶ 4 types of rotations
 - ▶ Left (L)
 - ▶ Right (R)
 - ▶ Left-right (LR)
 - ▶ Right-left (RL)

Left (L) Rotations

- ▶ Used after insertion to right subtree of right child
 - ▶ Height difference is +2 and height difference at right child is +1

Right (R) Rotations

- ▶ Used after insertion to right subtree of right child
 - ▶ Height difference is -2 and height difference at left child is -1

Left-right (LR) Rotations

- ▶ Used after insertion to right subtree of right child
 - ▶ Height difference is -2 and height difference at left child is +1

Right-left (RL) Rotations

- ▶ Used after insertion to right subtree of right child
 - ▶ Height difference is +2 and height difference at right child is -1

Rotation properties

- ▶ All rotations are local
 - ▶ Subtrees are not impacted
- ▶ All rotations are constant time (just pointer manipulation)
- ▶ BST property maintained

Time complexities

Operation	Runtime
Insert	$O(\log n)$
Erase	$O(\log n)$
Find	$O(\log n)$
Begin	$O(\log n)$ *
Lower bound	$O(\log n)$
Size	$O(1)$

* Could be implemented as $O(1)$ for frequent access to `begin()`

Some things to note

- ▶ `std::map` and `std::multimap` are also implemented as a balanced BST (each node has a key-value pair and compared by key)
- ▶ `std::set` lacks `rank()` operation.
 - ▶ `Rank(x)` is the x^{th} smallest value of the set
- ▶ Be careful incrementing set iterator.
 - ▶ Each `it++` takes $O(\log n)$ time worst case
 - ▶ But STL implementation gives $O(1)$ time amortized after traversing entire tree.
 - ▶ `for (auto it = s.begin(); it != s.end(); it++) { /* constant work */ }`

Use Cases of `std::set`/`std::map`

- ▶ Maintaining unique elements (since `std::set` has no duplicates)
 - ▶ Especially useful if we are maintaining elements of custom data type that is easier to compare than hash
- ▶ Checking existence
 - ▶ Always consider:
 - ▶ Do I need elements to be sorted? (consider `unordered set/map`)
 - ▶ What is the range of possible values? (consider array)
- ▶ Maintaining smallest and largest elements
- ▶ Iterating in order

Use Cases of `std::set`/`std::map` in HFT

- ▶ In general, `std::set` should be avoided in low latency systems
 - ▶ Each insert requires heap allocation (slow)
 - ▶ $O(\log n)$ operations may be slow compared to array + caching
- ▶ Used in snapshot synthesizer in trading system (more in week 6)
 - ▶ Used to recover missed market updates from exchange due to UDP
 - ▶ Receives state of order book and new market updates
 - ▶ Stores it in `std::map` (mapping sequence number to market update information)
 - ▶ Sequence numbers need to be sorted to find start/end of snapshot and gaps
 - ▶ Not so latency sensitive since this is a rare occurrence and trading is paused during recovery

Exercises

- ▶ Compare set and vector
- ▶ Compare BST and balanced BST
- ▶ Implement BST recursive functions iteratively and compare speed
- ▶ Implement `std::multiset`
- ▶ Implement `std::map`
- ▶ Implement `set::rank` (hint: maintain subtree sizes)
- ▶ Implement AVL tree (hint: maintain node height and implement left/right rotation functions)
- ▶ Implement red-black tree
